ABSTRACT

Parts of two separate collisional orogens are investigated in this study. One is the Middle-Late Ordovician Taconic orogen in eastern New York and western Vermont, and the other is the active Himalayan orogen of southeastern Tibet. Part I through III deal with a strain history and associated fluid properties during the late Taconic event in the western margin of the orogen and adjacent foreland. Senses of slip along slickensided quartz-calcite veins in the melange belt and their field relationships suggest an extension event following the late Taconic thrusting (Part I). In Part II, oxygen isotope analysis of veins and host rocks, and fluid inclusion and stable isotope data from veins/vug-fillings are presented. I propose that metamorphic waters were expelled from the internal Taconic orogen and subject to a large-scale westward migration principally within the detachment zone. In Part III, orogen-parallel normal faults newly mapped in the Bald Mountain region also show the regional late extension of the orogen, induced by breakoff of the eastward-subducted slab. The extension probably started in the New York promontory and propagated northward. Strike-slip cross faults/veins were formed by differential motions induced by northward propagation of the tear point and a coupled marginal pull from the dangling slab edge. Part IV addresses structures and uplift/exhumation mechanism of the Namche Barwa massif, southeastern Tibet. The Namche Barwa massif is a dome-antiformal active basement uplift, where a part of the Higher Himalaya with the Tethyan-metasedimentary cover have been structurally uplifted through a tectonic half window marked by the Indus-Tsangpo suture. The western-northern massif margin predominantly contains the Himalayan fabrics locally overprinted by younger fabrics. The Nam-la Thrust Zone recording intense south- to southwest-directed thrust motion defines the southern boundary of the recently and rapidly exhumed massif core region. Anomalous lithospheric thickening is suggested as the most plausible mechanism causing the anomalous uplift/exhumation of the Namche Barwa massif.

To my mother who has been always dedicated to family

ACKNOWLEDGEMENTS

I thank my advisor Dr. William S. F. Kidd for the exceptional opportunity to study the Namche Barwa region that provided me a chance to learn tectonics of the Tibet/Himalaya as well as financial support. I also thank him for introducing the Taconic geology, one of classic orogens which still has a lot to explore. Both regions have provided an excellent opportunity to obtain the geological experience I have pursued, and truly his advice and continuous encouragement have been an invaluable aid to complete this study. I have learned a lot from numerous discussions with him. I thank Drs. John Garver and John Arnason for many helpful comments which substantially improved the manuscript. I am grateful to Dr. Win Means for his concern and many great conversations. I am indebted to Dr. Scott Johnson for generous loan of universal stage parts. The well log data were provided by the New York State Department of Environmental Conservation. I am also grateful to Dr. Bruce Taylor for the stable isotope analysis and for kind messages about sample preparation. Mr. Steve Howe set up the heating/cooling stage and helped start fluid inclusion analysis. I appreciate Dr. Vince Idone for his concern and administrative support from Diana Paton and Sally Marsh. I thank residents in the Bald Mountain region for their generosity to allow access to their properties and guidance to some outcrops. I am very grateful to my friends, Youshe Li and Bin Zhu for much help and encouragement throughout graduate study, which will be always remembered. I was lucky to have Adam Schoonmaker as a fellow graduate student, and thank him. I also thank another friend Antonios Marsellos for his help and concern. I deeply thank my parents, sisters, and brother for their concern and heartfelt love. Without

their dedicated help, this study might not have been completed. Finally, I extend hearty thanks to Daehaeng for her Dharma talk and to Buddha's wisdom.

This study was supported by the National Science Foundation, American Association of Petroleum Geologists, and different units of the University at Albany (Benevolent Association, Graduate Student Organization, and Department of Earth and Atmospheric Sciences).
